Why Dive into Advanced Calculus?

Before we embark on solving problems, it's worth considering **why** we push ourselves into these more complex areas. Advanced calculus, also known as multivariable calculus, vector calculus, or mathematical analysis, is crucial for: **Scientific and Engineering Advancement:** From fluid dynamics and electromagnetism to quantum mechanics and machine learning, advanced calculus is the bedrock of many scientific and engineering disciplines. **Data Science and Machine Learning:** Understanding optimization, gradient descent, and probability distributions in higher dimensions relies heavily on advanced calculus. **Economic Modeling:** Complex financial

models, risk analysis, and optimization problems in economics often utilize the tools of advanced calculus. **Pure Mathematics:** For those pursuing pure mathematics, advanced calculus is a fundamental building block for further study in areas like differential geometry, topology, and real analysis.

Key Areas of Advanced Calculus and Associated Problems

Advanced calculus is a vast landscape. We'll focus on some of the most impactful and frequently encountered areas, along with representative **advanced calculus problems and solutions**.

1. Multivariable Functions and Partial Derivatives

At its core, advanced calculus extends the concepts of single-variable calculus to functions of two or more variables. This means we're no longer looking at the slope of a curve, but the rate of change of a surface or a higher-dimensional object.

Concept: A multivariable function $f(x, y)$ describes a relationship where the output depends on the values of multiple input variables. **Partial derivatives** measure how the output changes with respect to *one* of these variables, holding all others constant. **Example Problem:** Consider the function $f(x, y) = x^3y^2 - 5xy + y^4$. Find the partial derivatives $\frac{\partial f}{\partial x}$ and $\frac{\partial f}{\partial y}$. Then, evaluate these partial derivatives at the point $(2, 1)$.

Solution: To find $\frac{\partial f}{\partial x}$, we treat y as a constant and differentiate with respect to x : $\frac{\partial}{\partial x}(x^3y^2 - 5xy + y^4) = 3x^2y^2 - 5y$.

$\frac{\partial f}{\partial x} = \frac{\partial}{\partial x}(x^3y^2 - 5xy + y^4)$
 $\frac{\partial f}{\partial x} = 3x^2y^2 - 5y$
 Now, to find $\frac{\partial f}{\partial y}$, we treat x as a constant and differentiate with respect to y :
 $\frac{\partial f}{\partial y} = \frac{\partial}{\partial y}(x^3y^2 - 5xy + y^4)$
 $\frac{\partial f}{\partial y} = 2x^3y - 5x + 4y^3$
 To evaluate at $(2, 1)$:
 $\frac{\partial f}{\partial x}(2, 1) = 3(2)^2(1)^2 - 5(1) = 3(4)(1) - 5 = 12 - 5 = 7$
 $\frac{\partial f}{\partial y}(2, 1) = 2(2)^3(1) - 5(2) + 4(1)^3 = 2(8)(1) - 10 + 4 = 16 - 10 + 4 = 10$
Keywords: partial derivatives, multivariable functions, rate of change, independent variables, dependent variable, calculus problems solved.

2. Gradient, Divergence, and Curl: The Power of Vector Calculus

Vector calculus introduces us to fields – quantities that have a magnitude and direction at every point in space. **Gradient**, **divergence**, and **curl** are fundamental operators that describe the behavior of these fields. **Concept:** **Gradient** (∇f): For a scalar function $f(x, y, z)$, the gradient is a vector pointing in the direction of the greatest rate of increase of the function, with magnitude equal to that rate. **Divergence** ($\nabla \cdot \mathbf{F}$): For a vector field $\mathbf{F} = \langle P, Q, R \rangle$, divergence measures the extent to which the field is "spreading out" from a point (like a source or sink). **Curl** ($\nabla \times \mathbf{F}$): For a vector field $\mathbf{F}$, curl measures the tendency of the field to "rotate" around a point. **Example Problem:** Let $f(x, y, z) =$

$x^2y - yz^3$. a) Find the gradient of f . b) Let $\mathbf{F}(x, y, z) = \langle xy, y^2z, xz^2 \rangle$. Find the divergence of $\mathbf{F}$. c) Calculate the curl of $\mathbf{F}$.

Solution: a) The gradient is given by $\nabla f = \langle \frac{\partial f}{\partial x}, \frac{\partial f}{\partial y}, \frac{\partial f}{\partial z} \rangle$.
 $\frac{\partial f}{\partial x} = 2xy$
 $\frac{\partial f}{\partial y} = x^2 - z^3$
 $\frac{\partial f}{\partial z} = -3yz^2$
 So, $\nabla f = \langle 2xy, x^2 - z^3, -3yz^2 \rangle$.
 b) The divergence is $\nabla \cdot \mathbf{F} = \frac{\partial P}{\partial x} + \frac{\partial Q}{\partial y} + \frac{\partial R}{\partial z}$,
 where $P=xy$, $Q=y^2z$, and $R=xz^2$.
 $\frac{\partial P}{\partial x} = y$
 $\frac{\partial Q}{\partial y} = 2yz$
 $\frac{\partial R}{\partial z} = 2xz$
 So, $\nabla \cdot \mathbf{F} = y + 2yz + 2xz$.
 c) The curl is given by:
 $\nabla \times \mathbf{F} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \frac{\partial}{\partial x} & \frac{\partial}{\partial y} & \frac{\partial}{\partial z} \\ xy & y^2z & xz^2 \end{vmatrix}$
 $= \mathbf{i} \left(\frac{\partial}{\partial y}(xz^2) - \frac{\partial}{\partial z}(y^2z) \right) - \mathbf{j} \left(\frac{\partial}{\partial x}(xz^2) - \frac{\partial}{\partial z}(xy) \right) + \mathbf{k} \left(\frac{\partial}{\partial x}(y^2z) - \frac{\partial}{\partial y}(xy) \right)$
 $= \mathbf{i} (0 - y^2) - \mathbf{j} (z^2 - 0) + \mathbf{k} (0 - x)$
 $= \langle -y^2, -z^2, -x \rangle$
Keywords: vector calculus, vector fields, gradient, divergence, curl, differential operators, fluid dynamics, electromagnetism, vector calculus problems.

3. Line Integrals and Surface Integrals: Measuring Along Curves and Surfaces

Line and surface integrals allow us to accumulate quantities along curves and over surfaces, respectively. These are essential for calculating work done by a force, mass of a wire, or flux through a surface. **Concept:**

Line Integral ($\int_C \mathbf{F} \cdot d\mathbf{r}$): Integrates a vector field $\mathbf{F}$ along a curve C .
Surface Integral ($\int_S \mathbf{F} \cdot d\mathbf{S}$): Integrates a vector field $\mathbf{F}$ over a surface S .
Example Problem:

Calculate the line integral of $\mathbf{F}(x, y) = \langle -y, x \rangle$ along the upper semicircle C of radius 1 centered at the origin, traversed counterclockwise.

Solution: We can parameterize the upper semicircle C by $\mathbf{r}(t) = \langle \cos t, \sin t \rangle$ for $0 \leq t \leq \pi$.

Then, $\mathbf{r}'(t) = \langle -\sin t, \cos t \rangle$. And $\mathbf{F}(\mathbf{r}(t)) = \langle -\sin t, \cos t \rangle$. The line integral is:

$$\begin{aligned} \int_C \mathbf{F} \cdot d\mathbf{r} &= \int_0^\pi \mathbf{F}(\mathbf{r}(t)) \cdot \mathbf{r}'(t) \, dt \\ &= \int_0^\pi \langle -\sin t, \cos t \rangle \cdot \langle -\sin t, \cos t \rangle \, dt \\ &= \int_0^\pi (\sin^2 t + \cos^2 t) \, dt \\ &= \int_0^\pi 1 \, dt = \pi \end{aligned}$$

Keywords: line integral, surface integral, vector calculus applications, work done, flux, parameterization, integration techniques, challenging calculus problems.

4. Green's Theorem, Stokes' Theorem, and the Divergence Theorem: Connecting Different Dimensions

These powerful theorems provide profound connections between integrals over different dimensional spaces. They are cornerstones of advanced calculus, simplifying complex calculations by allowing us to transform line integrals into double integrals, surface integrals into line integrals, or volume integrals into surface integrals. **Concept:** **Green's Theorem:**

Relates a line integral around a simple closed curve C in the xy -plane to a double integral over the region D enclosed by C .

Stokes' Theorem: Relates a line integral of a vector field $\mathbf{F}$ around a boundary curve C of a surface S to the surface integral of the curl of $\mathbf{F}$ over S .

Divergence Theorem: Relates a double integral of a vector field $\mathbf{F}$ over a closed surface S to a triple integral of the divergence of $\mathbf{F}$ over the solid region E bounded by S .

Example Problem (Divergence Theorem):

Use the Divergence Theorem to evaluate the flux of the vector field $\mathbf{F}(x, y, z) = \langle x^2, y^2, z^2 \rangle$ out of the unit sphere $x^2 + y^2 + z^2 = 1$.

Solution: The Divergence Theorem states $\iint_S \mathbf{F} \cdot d\mathbf{S} = \iiint_E \nabla \cdot \mathbf{F} \, dV$. First, find the divergence of $\mathbf{F}$: $\nabla \cdot \mathbf{F} = \frac{\partial}{\partial x}(x^2) + \frac{\partial}{\partial y}(y^2) + \frac{\partial}{\partial z}(z^2) = 2x + 2y + 2z$. Now, we need to evaluate the triple integral over the unit ball E : $\iiint_E (2x + 2y + 2z) \, dV$. Due to the symmetry of the unit ball and the linear nature of the integrand, the integrals of $2x$,

$\frac{\partial}{\partial y}$, and $\frac{\partial}{\partial z}$ over the ball are all zero. For example, $\iiint_E 2x \, dV = 0$ because for every point (x, y, z) in the ball, the point $(-x, y, z)$ is also in the ball, and their x -contributions cancel out. Thus, the total flux is 0. **Keywords:** Green's theorem, Stokes' theorem, divergence theorem, flux, volume integral, surface integral, line integral, fundamental theorems of calculus, advanced calculus solutions explained.

5. Infinite Series and Sequences: The Realm of the Infinitely Small (and Large)

Understanding the behavior of infinite sequences and series is crucial for approximating functions, solving differential equations, and exploring concepts like convergence and convergence tests. **Concept:** An infinite sequence is a list of numbers, while an infinite series is the sum of the terms of a sequence. Determining whether a series converges (sums to a finite value) or diverges is a key challenge. **Example**

Problem: Determine whether the series $\sum_{n=1}^{\infty} \frac{1}{n^2}$ converges or diverges. If it converges, find its sum. **Solution:** This is a well-known **p-series** of the form $\sum_{n=1}^{\infty} \frac{1}{n^p}$. For a p-series, it converges if $p > 1$ and diverges if $p \leq 1$. In this case, $p=2$, so the series converges. The sum of this particular series is a famous result from Fourier analysis and is known to be $\frac{\pi^2}{6}$. $\sum_{n=1}^{\infty} \frac{1}{n^2} = 1 + \frac{1}{4} + \frac{1}{9} + \frac{1}{16} + \dots = \frac{\pi^2}{6}$ **Keywords:** infinite series, sequences, convergence tests, p-series, Fourier series, power series,

calculus problems and solutions for students.

various fields.

For students and professionals alike, mastering advanced calculus is a journey that rewards perseverance.

Understanding the underlying principles and the strategic approaches to tackling these problems is crucial for academic success and professional advancement. We will explore common themes and provide

illustrative examples, demystifying some of the most formidable challenges in this field.

The Realm of Multivariable Calculus: Beyond Two Dimensions

Multivariable calculus extends the familiar concepts of single-variable calculus to functions of multiple variables. This opens up a vast landscape of problems involving surfaces, volumes, and vector fields in three or more dimensions. The complexities arise from dealing with partial derivatives, multiple integrals, and line and surface integrals.

Gradient, Divergence, and Curl: Navigating

Vector Fields

One of the cornerstones of multivariable calculus is the study of vector fields. These fields, which assign a vector to each point in space, are fundamental in physics, describing phenomena like fluid flow, electromagnetism, and gravitational forces. Understanding and manipulating these fields often involves calculating the gradient, divergence, and curl.

Problem Example: Work Done by a Force Field

Consider a force field $\mathbf{F}(x, y, z) = \langle yz, xz, xy \rangle$. Calculate the work done by this force

field in moving a particle along the helix $\mathbf{r}(t) = \langle \cos(t), \sin(t), t \rangle$ from $t=0$ to $t=2\pi$.

Solution Approach: The work done by a force field $\mathbf{F}$ along a curve C is given by the line integral $\int_C \mathbf{F} \cdot d\mathbf{r}$. We parameterize the curve $\mathbf{r}(t)$ and its derivative $\mathbf{r}'(t) = \langle -\sin(t), \cos(t), 1 \rangle$.

Substituting the parameterization into the force field, we get $\mathbf{F}(\mathbf{r}(t)) = \langle t\sin(t), t\cos(t), \cos(t)\sin(t) \rangle$. The dot product $\mathbf{F}(\mathbf{r}(t)) \cdot$

$\mathbf{r}'(t)$ becomes $(t\sin(t))(-\sin(t)) + (t\cos(t))(\cos(t)) + (\cos(t)\sin(t))(1) = -t\sin^2(t) + t\cos^2(t) + \sin(t)\cos(t)$. This simplifies to $t\cos(2t) + \frac{1}{2}\sin(2t)$. The work done is then the integral of this expression from $t=0$ to $t=2\pi$: $W = \int_0^{2\pi} \left(t\cos(2t) + \frac{1}{2}\sin(2t) \right) dt$. Using integration by parts for the first term and direct integration for the second, we find $W = 0$. This is a significant result, indicating that the force field might be conservative or that the work done over this closed loop is zero.

This problem exemplifies the

application of line integrals, a crucial concept in vector calculus.

Understanding the physical interpretation of work done by a force field adds another layer of comprehension.

Multiple Integrals and Change of Variables

Evaluating integrals over regions in higher dimensions often requires powerful techniques, chief among them being the change of variables. This allows us to transform complex integration domains into simpler ones, often by switching to polar, cylindrical, or spherical coordinates.

Problem Example: Volume Calculation using Spherical Coordinates

Find the volume of the region bounded by the sphere $x^2 + y^2 + z^2 = 4$ and above the cone $z = \sqrt{x^2 + y^2}$.

Solution Approach: The region is best described in spherical coordinates.

The sphere $x^2 + y^2 + z^2 = 4$ translates to $\rho^2 = 4$, or $\rho = 2$. The cone $z = \sqrt{x^2 + y^2}$ corresponds to the angle $\phi = \pi/4$ in spherical coordinates. The volume element in spherical coordinates is $dV = \rho^2 \sin(\phi) d\rho d\phi d\theta$. The limits of integration are: $0 \leq \rho \leq 2$, 0

$\leq \phi \leq \pi/4$, and $0 \leq \theta \leq 2\pi$. The volume is then given by

the triple integral: $V =$

$$\int_0^{2\pi} \int_0^{\pi/4} \int_0^2 \rho^2 \sin(\phi) d\rho d\phi d\theta$$

Evaluating this integral, we get:

$$V = \int_0^{2\pi} d\theta$$

$$\int_0^{\pi/4} \sin(\phi) d\phi \int_0^2 \rho^2 d\rho$$

$$= (2\pi) [-\cos(\phi)]_0^{\pi/4}$$

$$= \left[\frac{\rho^3}{3} \right]_0^2$$

$$= (2\pi) (-\cos(\pi/4) - (-\cos(0)))$$

$$= \left(\frac{8}{3} \right) (2\pi)$$

$$= (2\pi) \left(1 - \frac{\sqrt{2}}{2} \right)$$

$$= \left(\frac{8}{3} \right) (2\pi) = \frac{16\pi}{3} \left(1 - \frac{\sqrt{2}}{2} \right)$$

$$= \frac{16\pi}{3} \left(1 - \frac{\sqrt{2}}{2} \right)$$

$$= \frac{16\pi}{3} \left(1 - \frac{\sqrt{2}}{2} \right)$$

$$= \frac{16\pi}{3} \left(1 - \frac{\sqrt{2}}{2} \right)$$

problem showcases the power of changing coordinate systems to simplify complex geometric integration.

The World of Differential Equations: Modeling Change

Differential equations are the language of change. They describe systems that evolve over time or space, from population dynamics and heat diffusion to the motion of celestial bodies. Advanced calculus problems in this area often involve solving complex ordinary differential equations (ODEs) and partial differential equations (PDEs).

Solving Second-Order Linear ODEs with Constant Coefficients

These equations are ubiquitous in physics and engineering, describing phenomena like simple harmonic motion and RLC circuits. The solution method hinges on finding the roots of the characteristic equation.

Problem Example: Damped Harmonic Oscillator

Consider a mass-spring system with a damping force. The equation of motion is given by

$m \frac{d^2x}{dt^2} + c \frac{dx}{dt} + kx = 0$, where $m=1$, $c=2$, and $k=5$. Find the general solution for $x(t)$, assuming

initial conditions $x(0)=1$ and $x'(0)=0$.

Solution Approach: The characteristic equation is $r^2 + 2r + 5 = 0$. Using the quadratic formula, $r = \frac{-2 \pm \sqrt{2^2 - 4(1)(5)}}{2(1)} = \frac{-2 \pm \sqrt{4 - 20}}{2} = \frac{-2 \pm \sqrt{-16}}{2} = \frac{-2 \pm 4i}{2} = -1 \pm 2i$.

Since the roots are complex conjugates ($r = \alpha \pm \beta i$), the general solution is of the form $x(t) = e^{\alpha t}(C_1 \cos(\beta t) + C_2 \sin(\beta t))$. In this case, $\alpha = -1$ and $\beta = 2$, so $x(t) = e^{-t}(C_1 \cos(2t) + C_2 \sin(2t))$.

Now, we apply the initial conditions.

$x(0) = e^0(C_1 \cos(0) + C_2 \sin(0))$
 $= 1(C_1 \cdot 1 + C_2 \cdot 0) = C_1$.
 Thus, $C_1 = 1$. To find C_2 , we
 first find $x'(t)$: $x'(t) = -e^{-t}(C_1 \cos(2t) + C_2 \sin(2t)) + e^{-t}(-2C_1 \sin(2t) + 2C_2 \cos(2t))$
 At $t=0$, $x'(0) = -e^0(C_1 \cos(0) + C_2 \sin(0)) + e^0(-2C_1 \sin(0) + 2C_2 \cos(0))$.
 $0 = -1(1 \cdot 1 + 0) + 1(0 + 2C_2 \cdot 1) = -1 + 2C_2$.
 Solving for C_2 , we get $2C_2 = 1$,
 so $C_2 = 1/2$. The particular
 solution is $x(t) = e^{-t}(\cos(2t) + \frac{1}{2}\sin(2t))$.

This problem illustrates the
 systematic approach to solving ODEs,
 which is fundamental for
 understanding dynamic systems. The

characteristic equation is a key tool in this domain.

Introduction to Partial Differential Equations (PDEs)

While ODEs deal with functions of a single independent variable, PDEs involve functions of two or more. They are essential for describing phenomena in fields like fluid dynamics, heat transfer, and wave propagation. Solving PDEs is generally more complex than solving ODEs.

Problem Example: The Heat Equation (Conceptual)**

Consider the one-dimensional heat

equation: $\frac{\partial u}{\partial t} = \alpha^2 \frac{\partial^2 u}{\partial x^2}$, where $u(x, t)$ is the temperature at position x and time t , and α^2 is the thermal diffusivity. This equation models how heat diffuses through a material. Boundary and initial conditions are crucial for finding a unique solution. For instance, if we have a rod of length L with fixed temperatures at the ends ($u(0, t) = T_1$, $u(L, t) = T_2$) and an initial temperature distribution $u(x, 0) = f(x)$, the problem becomes a boundary value problem.

Solution Approach (Conceptual): The most common method for solving

such linear homogeneous PDEs with boundary conditions is the method of separation of variables. We assume a solution of the form $u(x, t) = X(x)T(t)$. Substituting this into the PDE, we get $X(x)T'(t) = \alpha^2 X''(x)T(t)$. Rearranging, we get $\frac{T'(t)}{\alpha^2 T(t)} = \frac{X''(x)}{X(x)}$. Since the left side depends only on t and the right side only on x , both sides must be equal to a constant, say $-\lambda$. This leads to two ODEs: $T'(t) = -\lambda \alpha^2 T(t)$ and $X''(x) = -\lambda X(x)$. Solving these and applying boundary conditions leads to a series solution. While a full solution is beyond a

simple example, this conceptual outline highlights the core strategy for many PDE problems.

Understanding the physical meaning of the equation and its parameters is key to interpreting the solutions.

Real Analysis: The Rigor of Continuity and Convergence

Real analysis provides the rigorous foundation for calculus. It deals with the properties of real numbers, sequences, series, continuity, differentiability, and integration in a formal, axiomatic way. Advanced problems in real analysis often involve proofs and understanding subtle nuances.

Sequences and Series Convergence

Determining whether an infinite sequence converges to a limit or an infinite series sums to a finite value are fundamental tasks in real analysis. Various convergence tests are employed.

Problem Example: Convergence of an Alternating Series

Determine whether the series $\sum_{n=1}^{\infty} (-1)^{n+1} \frac{1}{n}$ converges. If it converges, is the convergence conditional or absolute?

Solution Approach: This is an alternating series. We can apply the Alternating Series Test. Let $b_n =$

$\frac{1}{n}$. 1. $b_n > 0$ for all $n \geq 1$. 2. $b_n = \frac{1}{n}$ is a decreasing sequence since $\frac{1}{n+1} < \frac{1}{n}$. 3. $\lim_{n \rightarrow \infty} b_n = \lim_{n \rightarrow \infty} \frac{1}{n} = 0$. Since all conditions of the Alternating Series Test are met, the series $\sum_{n=1}^{\infty} (-1)^{n+1} \frac{1}{n}$ converges. This series is known as the alternating harmonic series.

To check for absolute convergence, we consider the series of the absolute values of the terms:

$\sum_{n=1}^{\infty} |(-1)^{n+1} \frac{1}{n}| = \sum_{n=1}^{\infty} \frac{1}{n}$. This is the harmonic

series, which is known to diverge (a p -series with $p=1$). Since the series converges but the series of absolute values diverges, the convergence is conditional.

This problem highlights the importance of understanding different convergence tests and the distinction between conditional and absolute convergence, crucial concepts in real analysis.

Questions & Answers About advanced calculus problems and solutions

No	Question	Answer
1	What's a common pitfall when evaluating improper integrals, and how can it be avoided?	A common pitfall is forgetting to check for convergence before attempting to find a definite value. Solutions often involve correctly applying limits to the integral's bounds and analyzing the behavior of the integrand as it approaches infinity or a discontinuity. If the limit doesn't exist or is infinite, the integral diverges.
2	How can multivariable calculus help us optimize functions with multiple constraints?	Lagrange multipliers are the go-to technique. They allow us to find the extrema of a function subject to one or more equality constraints by introducing a new variable for each constraint and solving a system of equations involving gradients.

3	What's the intuition behind using line integrals to calculate work done by a force field?	Imagine moving a particle along a path. At each infinitesimal step, the work done is the component of the force in the direction of motion multiplied by the distance. A line integral sums these infinitesimal work contributions along the entire path, giving the total work done.
4	When dealing with surface integrals, what's the key difference between integrating a scalar function and a vector field, and why does it matter?	Integrating a scalar function over a surface gives a scalar quantity (like the mass of a thin shell). Integrating a vector field (like flux) over a surface gives the net 'flow' of the field through that surface. The distinction is crucial for understanding physical phenomena like fluid flow or electric fields.
5	How does Green's Theorem simplify the calculation of area or circulation in 2D?	Green's Theorem relates a line integral around a simple closed curve to a double integral over the region enclosed by that curve. This means we can often convert a potentially difficult line integral into a simpler double integral, or vice-versa, for calculating area or the circulation of a vector field.
6	What are the conditions under which the Divergence Theorem is applicable, and what does it tell us?	The Divergence Theorem applies to a differentiable vector field and a solid region with a piecewise smooth boundary. It states that the flux of the vector field out of the boundary of the region is equal to the triple integral of the divergence of the field over the region itself, relating surface behavior to volume behavior.

7	How do partial differential equations (PDEs) arise in real-world problems, and what's a typical approach to solving a simple one?	PDEs describe phenomena where a quantity depends on multiple independent variables (e.g., temperature distribution in space and time). Simple problems, like the heat equation, might be solved using separation of variables to reduce the PDE into ordinary differential equations, which are then solved and combined.
8	What's the significance of the Jacobian determinant in change of variables for multiple integrals?	The Jacobian determinant acts as a scaling factor for infinitesimal area or volume elements when transforming coordinates. It accounts for how the transformation distorts space, ensuring that the resulting integral in the new coordinate system correctly represents the original integral's value.
